A Newton method is used to solve the resulting set of nonlinear equations. This approach limits the required number of time discretization steps (here 80 time steps per RF cycle). Doubling the number of grid points and time steps resulted in 10<sup>-2</sup> and 10<sup>-4</sup> for the maximum relative changes of the partial pressures (SiH<sub>4</sub>, H<sub>2</sub>, and Si<sub>2</sub>H<sub>6</sub>...

Abstract This chapter concerns iterative solution techniques for linear systems of equations arising from the discretization of elliptic boundary value problems. Very often huge systems are obtained, with condition numbers which depend on the meshsize h of the triangulation, which typically grow in proportion to h<sup>-2</sup>.

The forward Euler method  $\approx + - = -$  yields  $+ = -$  for each  $\approx, \dots$ . This is an explicit formula for  $+ -$ . Backward Euler method. With the backward Euler method  $+ - = - +$  one finds the implicit equation  $+ + = +$  (compare this with formula (3) where  $+ =$  was given explicitly rather than as an unknown in an equation). This is a quadratic equation, having one negative and one positive root.

Domain decomposition methods are powerful iterative methods for solving systems of algebraic equations arising from the discretization of partial differential equations (PDEs) by, e.g., nite elements. The computational domain, i.e., the domain where the PDE is defined and must be solved, is decomposed into overlapping or nonoverlapping subdomains.

### Domain Decomposition Methods for Mortar Finite Elements

Note that the final discrete systems resulted from the discretization proposed by , , have block structure, so the block iterative methods can be directly applied (e.g., block Gauss-Seidel iterative method , ). Although the pursuit of "decoupling" between scatterers is similar to these works, the derivation of our iterative algorithm is from the boundary integral equations that leads to more effective communication between scatterers.

Discretization methods are used to chop a continuous function (i.e., the real solution to a system of differential equations in CFD) into a discrete function, where the solution values are defined at each point in space and time. Discretization simply refers to the spacing between each point in your solution space.
