Engine Cylinder Deactivation

In a nutshell, cylinder deactivation is simply keeping the intake and exhaust valves closed through all cycles for a particular set of cylinders in the engine. Depending on the design of the engine, valve actuation is controlled by one of two common methods:

Cylinder Deactivation & Variable Engine Displacement

Cylinder Deactivation, or CDA, is a technique in multi-cylinder engines where a combination of cylinders are systematically disabled, effectively reducing the engine's displacement, improving overall engine efficiency and fuel economy. CDA is

Unfortunately, cylinder deactivation still carries a bit of stigma among some older drivers with long memories, and it stems from General Motors. At the time of the second national fuel crisis, in 1979, GM decided to manufacture an engine dubbed the V8-6-4. As its name suggests, this was essentially a V-8 engine, like many others in the GM lineup.

Cylinder Deactivation: How It Can Save Fuel | Shopping ...

Cylinder deactivation provides owners with the best of both worlds – V8 power when it's needed, and four-cylinder fuel economy and emissions levels when it's not. Typically, when a cylinder is deactivated, the system closes its intake and exhaust valves. It also stops injecting fuel into the deactivated cylinder.

When an engine fitted with cylinder deactivation detects the car is cruising, a solenoid valve opens and a system forces the valves shut, preventing fuel and air from reaching some of the cylinders. This means combustion is only taking place in half of the engine and thus much less fuel is burned when cruising.

What is cylinder deactivation? | carwow

Cylinder deactivation works on the same principle as variable valve timing and lift: An engine needs different amounts of fuel for different types of work. Take a V-8 engine, for example. A V-8 engine has eight cylinders. Whenever the engine is on, all eight of those cylinders are working, burning up fuel and air.

Cylinder deactivation has been around for years and is present in a lot of European cars with no adverse effects. Ford have used it in their 3 cylinder Ecoboosts over here for 4 or 5 years and those engines are bullet proof. Joek, tlondon, MagicMike and 7 others like this. Mikthehun1

Oh no, here comes the cylinder deactivation nonsense ...

Cylinder deactivation is used to reduce the fuel consumption and emissions of an internal combustion engine during light-load operation. In typical light-load driving the driver uses only around 30 percent of an engine's maximum power. In these conditions, the throttle valve is nearly closed, and the engine needs to work to draw air.
